

# Essay about life span development

Life

**ASSIGN  
BUSTER**

The study of life development grew out of Darwin's desire to understand evolution. The first study of children was published by G. Stanley Hall. Hall's book introduced norms and adolescence to scientists (Boyd & Bee, 2006). Life is the period of time from conception extending to death. This paper will define the development of humans throughout the life and describe the characteristics of the life perspective. Human development domains and periods will be identified and contemporary concerns as related to life development will be identified. Life Development Defined

Life development is a process beginning at conception that continues until death. The progression initiates with the emergence of a fetus from a one-celled organism. As the unborn child enters the world the environment in which the child exists begins to influence the child's development (WGBH Educational Foundation, 2001). Life development can be defined as a methodical, intra-individual change associated with progressions corresponding to age. The development progresses in a manner implicating the level of functioning. According to Levinson the life cycle consists of four 25 year eras.

The main developmental periods are child and adolescence, early adulthood, middle adulthood and late adulthood. Each era's transition involves a necessary change in the character of the individual's life and sometimes takes up to six years to complete the change (Smith, 2009). The study of human development began with Darwin and other evolutionists. Darwin thought if he studied human development he could further prove his theory of evolution (Boyd & Bee, 2006). Characteristics of the Life Perspective The

lifeperspective argues that significant modifications take place throughout development.

The lifelong perspective consists of a development of humans that is multidimensional, multidirectional, plastic, multidisciplinary, and contextual. The development involves growth, maintenance and regulation. Changes that occur should be interpreted in a manner that considers the culture and context of the occurrences. Through the perspective comprehensions of the modifications of adulthood have gained as much importance as those occurring in childhood; an understanding from other disciplines in turn have increased importance in human development.

According to Paul Baltes, humans have the capacity of plasticity or positive change to environmental difficulties throughout life. Baltes additionally contributed to the understanding of the positive characteristics of growing old such as learning ways to compensate and overcome (Boyd & Bee, 2006).

**Human Development Domains** The domains of development are categories used by scientists. The categories include, physical, cognitive and social domains characterize human development. The physical domain is characterized by how humans grow and change physically, specifically during childhood and adolescence.

This domain includes how humans view the world as development progresses as a result of developing vision. Adjustments in the way the world is viewed as the body develops are also included in this domain. The cognitive domain is concerned with how learning occurs and why memory deteriorates during old age. The social domain contains adjustment in

variables within social situations such as personality research, social skills and developing relationships. All the domains operate together and are affected by each other (Boyd & Bee, 2006).

### Human Development Periods

Human development periods span the lifetime from conception to the end of life. These periods are as follows, prenatal, early, middle and late childhood. As the child grows and approaches adulthood the periods are adolescence, early, middle and late adulthood. Numerous theories about the periods of development and the movement from one period to the next exist. Various theories attempt to define how movement from one level to the next level of development occurs. The three major families include psychoanalytic, learning and cognitive theories (Boyd & Bee, 2006).

### Contemporary Concerns in Lifespan Development

Nature versus nurture is one of the many contemporary concerns in lifespan development. Additional concerns in the area of development include continuity and discontinuity. Nature and nurture concerns surround the basis of development. The issue lies in determining the weather genetics or environment influence development. The concern of continuity and discontinuity's impact on development lies in relationship development. "The question is whether age-related change is primarily a matter of amount or degree (the continuity side of the debate) or more commonly involves changes in type or kind (the discontinuity side)" (Boyd & Bee, 2006, p. ).

**Conclusion** Development of the lifespan began with Darwin and continues to intrigue psychologists and scientists today. An understanding of how humans develop consists of the domains of physical, cognitive and social advances.

The domains occur throughout prenatal, childhood and adult development. As the field expands the controversy of nature versus nurture and continuity and discontinuity continue to perplex those within the field. Freud advanced a theory of personality development that centered on the effects of the sexual pleasure drive on the individual psyche.

At particular points in the developmental process, he claimed, a single body part is particularly sensitive to sexual, erotic stimulation. These erogenous zones are the mouth, the anus, and the genital region. The child's libido centers on behavior affecting the primary erogenous zone of his age; he cannot focus on the primary erogenous zone of the next stage without resolving the developmental conflict of the immediate one. A child at a given stage of development has certain needs and demands, such as the need of the infant to nurse.

Frustration occurs when these needs are not met; Overindulgence stems from such an ample meeting of these needs that the child is reluctant to progress beyond the stage. Both frustration and overindulgence lock some amount of the child's libido permanently into the stage in which they occur; both result in a fixation. If a child progresses normally through the stages, resolving each conflict and moving on, then little libido remains invested in each stage of development.

But if he fixates at a particular stage, the method of obtaining satisfaction which characterized the stage will dominate and affect his adult personality. The Oral Stage The oral stage begins at birth, when the oral cavity is the primary focus of libidal energy. The child, of course, preoccupies himself

with nursing, with the pleasure of sucking and accepting things into the mouth. The oral character who is frustrated at this stage, whose mother refused to nurse him on demand or who truncated nursing sessions early, is characterized by pessimism, envy, suspicion and sarcasm.

The overindulged oral character, whose nursing urges were always and often excessively satisfied, is optimistic, gullible, and is full of admiration for others around him. The stage culminates in the primary conflict of weaning, which both deprives the child of the sensory pleasures of nursing and of the psychological pleasure of being cared for, mothered, and held. The stage lasts approximately one and one-half years. The Anal Stage At one and one-half years, the child enters the anal stage.

With the advent of toilet training comes the child's obsession with the erogenous zone of the anus and with the retention or expulsion of the feces. This represents a classic conflict between the id, which derives pleasure from expulsion of bodily wastes, and the ego and superego, which represent the practical and societal pressures to control the bodily functions. The child meets the conflict between the parent's demands and the child's desires and physical capabilities in one of two ways: Either he puts up a fight or he simply refuses to go.

The child who wants to fight takes pleasure in excreting maliciously, perhaps just before or just after being placed on the toilet. If the parents are too lenient and the child manages to derive pleasure and success from this expulsion, it will result in the formation of an anal expulsive character. This character is generally messy, disorganized, reckless, careless, and defiant.

Conversely, a child may opt to retain feces, thereby spiting his parents while enjoying the pleasurable pressure of the built-up feces on his intestine.

If this tactic succeeds and the child is overindulged, he will develop into an anal retentive character. This character is neat, precise, orderly, careful, stingy, withholding, obstinate, meticulous, and passive-aggressive. The resolution of the anal stage, proper toilet training, permanently affects the individual propensities to possession and attitudes towards authority. This stage lasts from one and one-half to two years. The Phallic Stage The phallic stage is the setting for the greatest, most crucial sexual conflict in Freud's model of development.

In this stage, the child's erogenous zone is the genital region. As the child becomes more interested in his genitals, and in the genitals of others, conflict arises. The conflict, labeled the Oedipus complex (The Electra complex in women), involves the child's unconscious desire to possess the opposite-sexed parent and to eliminate the same-sexed one. In the young male, the Oedipus conflict stems from his natural love for his mother, a love which becomes sexual as his libidal energy transfers from the anal region to his genitals.

Unfortunately for the boy, his father stands in the way of this love. The boy therefore feels aggression and envy towards this rival, his father, and also feels fear that the father will strike back at him. As the boy has noticed that women, his mother in particular, have no penises, he is struck by a great fear that his father will remove his penis, too. The anxiety is aggravated by the threats and discipline he incurs when caught masturbating by his

parents. This castration anxiety outstrips his desire for his mother, so he represses the desire.

Moreover, although the boy sees that though he cannot possess his mother, because his father does, he can possess her vicariously by identifying with his father and becoming as much like him as possible: this identification indoctrinates the boy into his appropriate sexual role in life. A lasting trace of the Oedipal conflict is the superego, the voice of the father within the boy. By thus resolving his incestuous conundrum, the boy passes into the latency period, a period of libidinal dormancy. On the Electra complex, Freud was more vague.

The complex has its roots in the little girl's discovery that she, along with her mother and all other women, lack the penis which her father and other men possess. Her love for her father then becomes both erotic and envious, as she yearns for a penis of her own. She comes to blame her mother for her perceived castration, and is struck by penis envy, the apparent counterpart to the boy's castration anxiety. The resolution of the Electra complex is far less clear-cut than the resolution of the Oedipus complex is in males; Freud stated that the resolution comes much later and is never truly complete.

Just as the boy learned his sexual role by identifying with his father, so the girl learns her role by identifying with her mother in an attempt to possess her father vicariously. At the eventual resolution of the conflict, the girl passes into the latency period, though Freud implies that she always remains slightly fixated at the phallic stage. Fixation at the phallic stage develops a

phallic character, who is reckless, resolute, self-assured, and narcissistic--excessively vain and proud.

The failure to resolve the conflict can also cause a person to be afraid or incapable of close love; Freud also postulated that fixation could be a root cause of homosexuality. Latency Period The resolution of the phallic stage leads to the latency period, which is not a psychosexual stage of development, but a period in which the sexual drive lies dormant. Freud saw latency as a period of unparalleled repression of sexual desires and erogenous impulses. During the latency period, children pour this repressed libidinal energy into asexual pursuits such as school, athletics, and same-sex friendships.

But soon puberty strikes, and the genitals once again become a central focus of libidinal energy. The Genital Stage In the genital stage, as the child's energy once again focuses on his genitals, interest turns to heterosexual relationships. The less energy the child has left invested in unresolved psychosexual developments, the greater his capacity will be to develop normal relationships with the opposite sex. If, however, he remains fixated, particularly on the phallic stage, his development will be troubled as he struggles with further repression and defenses.
