

The are not only
natural cycles but
also

[Environment](#), [Global Warming](#)

The main causes of global warming is to have a large amount of carbon dioxide (CO₂) in the atmosphere.

They contributed to increase in temperature in the planet. People consume such fossil fuels as coal, oil, and natural gas for energy or deforestation to have a place for plantations and pastures. Besides, there are a lot of gases in Earth's atmosphere known as "greenhouse gases" (GHGs) like methane (CH₄), nitrous oxide, They are pollutants making the problem become more serious.

In many poison gas existing in atmosphere, CO₂ is one of the greatest gas risks occurring in over many centuries. This gas will threaten not only climate of future but also progeny later (Climate hotmap, ten ho tac gia, nam). Human influence is also rapidly changing the climate. Scientists also authorities drew a conclusion on global warming that the temperature of the planet is increasing in at nearly twice the rate it was 50 years ago. Causes of this epidemic are not only natural cycles but also effect of GHGs released by people. IPCC- a groups specialized in researching and writing results about newest scientific findings about our planet, they declared that people living in the earth emitting toxic gas to environment in different ways. It is ignition of fossil fuels from vehicles, factories, industrialization, electricity product.

Landfills and agricultures also are impacted by methane (especially from the digestive systems of grazing animals), nitrous oxide from fertilizers, gas used for refrigeration and industrial processes,

However, each GHGs has a diverse effect on environment. To name a few, a particle of methane generates more than 20 times that of CO₂. Nitrous oxide is 300 times more influential than CO₂. Other gases have a high ability of heat-trapping, but none of these gases affect much warmth more than CO₂ does.

(Phan1, ho tac gia, nam) Another cause that contributed to increased emissions of GHGs is overpopulation. Nowadays, rapidly growing population has become a huge menace to natural environment as well as human-being. These responses have been made up many places for rice growing and cattle farming.

This makes methane go up dramatically and destroy our environment.

(Pakenham,. n. d) Human influence has been a very serious issue now because humans do not take care about the earth.

People cause global warming are more than natural causes global warming.

The earth has been changing for many years until now it is still changing due to modern lifestyle of everyone. Human activities include industrial production, burning fossil fuel, mining, cattle rearing or deforestation made our planet become worse and worse.
